Package: Corbi (via r-universe)

August 25, 2024

Version 0.6-2

Title Collection of Rudimentary Bioinformatics Tools

Description Provides a bundle of basic and fundamental bioinformatics tools, such as network querying and alignment, subnetwork extraction and search, network biomarker identification.

ByteCompile TRUE

Depends R (>= 3.0.2)

Imports Matrix, MASS, stats, CRF, igraph

Suggests knitr, rmarkdown, BiocParallel, matrixcalc, mpmi, fitdistrplus

VignetteBuilder knitr

License GPL (>= 2)

`Corbi-package` *Corbi - Collection of Rudimentary Bioinformatics Tools*

Description

This pakcage provides a bundle of basic and fundamental bioinformatics tools.

Details

These bioinformatics tools are developed by WuLab at Academy of Mathematics and Systems Science, Chinese Academy of Sciences.

Network querying and alignment:

- `net_query` Network querying method based on conditional random fields
- `net_query_batch` Batch processing version of `net_query`
- `net_align` Network alignment method based on conditional random fields

Subnetwork extraction and search:

- `get_subnets` Enumerate all subnetworks of limited size
- `extend_subnets` Extend subnetworks from smaller subnetworks
- `best_subnets` Search best subnetworks that maximize given objective function

Biomarker identification:

- `markrank` Biomarker identification and prioritization by integrating gene expression with biomolecular network

Differential expression analysis:

- `netDEG` Sample specific differential expression analysis

Data normalization:

- `URG_getFactor` Gene expression data normalization by the uniform ratio graph method

`best_subnets` *The best subnetworks*

Description

Search best subnetworks that maximize given objective functions.

Usage

```
best_subnets(
  func,
  net.matrix,
  max.size = 10,
  exhaust.size = 5,
  max.top = 10000
)
```

Arguments

func	The objective function to maximize
net.matrix	The adjacent matrix of network
max.size	The maximal size of subnetworks
exhaust.size	The maximal size of subnetworks that use exhaustive searching strategy
max.top	The maiximal number of top candidates kept for evaluation of next size, used in heuristic searching strategy

Details

Enumerate and search the best subnetworks that maximize given objective function. If the size of subnetworks <= exhaust.size, exact exhaustive searching is applied, otherwise, heuristic searching algorithm is used.

Value

A list with the following two components:

subnets	The list of top subnetworks in different sizes
obj.values	The list of objective values of corresponding subnetworks

See Also

get_subnets, extend_subnets

Examples

```
library(Corbi)
net <- matrix(FALSE, nrow=10, ncol=10)
net[sample.int(100, 20)] <- TRUE
net <- net | t(net)
func <- function(subnet) max(subnet) - min(subnet)
result <- best_subnets(func, net, 5)
```

---

column *Extract a column from a matrix*

Description

Extract a specified column from a sparse matrix rapidly

Usage

```
column(m, i)
```

Arguments

m	The matrix
i	The column index

Details

This function implements faster column extraction algorithm for the CsparseMatrix class in the package **Matrix**.

Value

This function will return the specified column as a vector of corresponding type.

---

extend_subnets *Extend subnetworks from smaller subnetworks*

Description

Extend subnetworks by pairwise overlapping two sets of smaller subnetworks.

Usage

```
extend_subnets(subnet1, subnet2, size = 0)
```

Arguments

subnet1	The matrix representing the first set of subnetworks
subnet2	The matrix representing the second set of subnetworks
size	The desired size of extended subnetworks

Details

Enumerate all possible subnetworks of desired size by pairwise overlapping two sets of subnetworks of size s1 and s2. The desired size should be between max(s1,s2)+1 and s1+s2-1. Invalid desired size will be replaced by the minimum allowed value max(s1,s2)+1.

Value

A matrix represents the extended subnetworks, in which each row represents a subnetwork.

Examples

```
library(Corbi)
net <- matrix(FALSE, nrow=10, ncol=10)
net[sample.int(100, 20)] <- TRUE
net <- net | t(net)
subnets <- get_subnets(net, 3)
subnets[[4]] <- extend_subnets(subnets[[3]], subnets[[2]], 4)
```

get_adjusted_deg_diff *Calculate adjusted degree differences for given network*

Description

Calculate the adjusted degree differences for all genes in the given network.

Usage

```
get_adjusted_deg_diff(net, log.expr.val, scale.degree = FALSE, p = 0.5)
```

Arguments

net	The binary adjacent matrix of differential expression ratio network.
log.expr.val	Numeric vector containing the logarithmic scale gene expression values.
scale.degree	Logical variable indicating whether the degree values are scaled according to the dropout rate.
p	The parameter for calculating the adjusted degree differences.

Value

This function will return a list with the following components:

diff	A numeric vector containing the adjusted degree differences of all genes.
degree	A list containing the raw degree differences and sums of all genes.

get_diff_ratio_net *Construct differential expression ratio network*

Description

Construct the differential expression ratio network for a single sample.

Usage

```
get_diff_ratio_net(
  ref.ratio.dist,
  expr.val,
  log.expr = FALSE,
  scale.degree = FALSE
)
```

Arguments

ref.ratio.dist	The expression ratio distribution profile returned by get_ratio_distribution or get_ratio_distribution2.
expr.val	Numeric vector of gene expression values in the sample.
log.expr	Logical variable indicating whether the input expression vector is in logarithmic scale.
scale.degree	Logical variable indicating whether the degree values are scaled according to the dropout rate.

Value

This function will return a list with the following components:

net	The binary adjacent matrix of differential expression ratio network.
diff	A numeric vector containing the adjusted degree differences of all genes.
degree	A list containing the raw degree differences and sums of all genes.

---

get_ratio_distribution

Calculate expression ratio distribution

Description

Calculate the lower and upper quantiles of expression ratios for each pair of genes, and estimate the parameters of negative binomial distribution from reference expression data.

Usage

```
get_ratio_distribution(
  ref.expr.matrix,
  p.edge = 0.1,
  log.expr = FALSE,
  scale.degree = FALSE,
  use.parallel = FALSE
)
```

Arguments

ref.expr.matrix	The reference expression matrix. Each row represents a gene and each column represents a sample.
p.edge	The expected probability of edges in the expression ratio network for a normal sample.
log.expr	Logical variable indicating whether the input expression matrix is in logarithmic scale.

scale.degree	Logical variable indicating whether the degree values are scaled according to the dropout rate.
use.parallel	Logical variable indicating to use the BiocParallel package to accelerate computation.

Value

This function will return a list with the following components:

LB	A numeric matrix with element [i,j] represents the lower quantile of expressioin ratios for gene pairs (i, j).
NB	A numeric vector with two elements: size and mu, which are the estimated parameters of negative binomial distribution.
p.edge	The used input parameter p.edge.

---

get_ratio_distribution2

Calculate expression ratio distribution

Description

Calculate the lower and upper quantiles of expression ratios after trimming the extreme values, and estimate the parameters of negative binomial distribution from reference expression data.

Usage

```
get_ratio_distribution2(
  ref.expr.matrix,
  p.edge = 0.1,
  p.trim = 0.3,
  log.expr = FALSE,
  scale.degree = FALSE,
  use.parallel = FALSE
)
```

Arguments

ref.expr.matrix	The reference expression matrix. Each row represents a gene and each column represents a sample.
p.edge	The expected probability of edges in the expression ratio network for a normal sample.
p.trim	The percentage of lower or upper extreme values to be trimmed from the expression ratios for each pair of genes.
log.expr	Logical variable indicating whether the input expression matrix is in logarithmic scale.

scale.degree	Logical variable indicating whether the degree values are scaled according to the dropout rate.
use.parallel	Logical variable indicating to use the BiocParallel package to accelerate computation.

Value

This function will return a list with the following components:

LB	A numeric matrix with element [i,j] represents the lower quantile of trimmed expressioin ratios for gene pairs (i, j).
NB	A numeric vector with two elements: size and mu, which are the estimated parameters of negative binomial distribution.
p.edge	The used input parameter p.edge.
p.trim	The used input parameter p.trim.

---

get_ratio_variance *Calculate expression ratio variances*

Description

Calculate the variances of expression ratios for each pair of genes.

Usage

```
get_ratio_variance(expr.matrix, log.expr = FALSE)
```

Arguments

expr.matrix	The expression matrix. Each row represents a gene and each column represents a sample.
log.expr	Logical variable indicating whether the input expression matrix is in logarithmic scale.

Value

This function will return a numeric matrix with element [i,j] represents the variance of expressioin ratios for gene pairs (i, j).

get_shortest_distances *Calculate shortest distances of unweighted network*

Description

Calculate all pairs of shortest distances of unweighted network

Usage

```
get_shortest_distances(
  net.matrix,
  source.nodes = rep_len(TRUE, dim(net.matrix)[1])
)
```

Arguments

net.matrix	Logical adjacency matrix of given unweighted network
source.nodes	Logical vector to indicate the source nodes that need to calculate the shortest distances

Details

This function calculates all pairs of shortest distances of unweighted network by using breadth-first-search (BFS) algorithm.

Value

This function will return the shortest distance matrix, where the element `[i, j]` is the shortest distance between node i and j. Value -1 means unreachable. If `source.nodes[i]` equals FALSE, the shortest distance from i to other nodes will not be calculated and the row i will be all -1.

get_subnets *All subnetworks of limited size*

Description

Enumerate all subnetworks of size <= `max.size` from given network.

Usage

```
get_subnets(net.matrix, max.size = 2)
```

Arguments

net.matrix	The adjacent matrix of network
max.size	The maximal size of subnetworks

Value

A list of generated subnetworks, with element i corresponds the subnetworks of size i. Each element is a matrix, in which each row represents a subnetwork.

Examples

```
library(Corbi)
net <- matrix(FALSE, nrow=10, ncol=10)
net[sample.int(100, 20)] <- TRUE
net <- net | t(net)
subnets <- get_subnets(net, 3)
```

---

kappa_score *Cohen's kappa score*

Description

Calculate Cohen's kappa score for two vectors.

Usage

```
kappa_score(x1, x2)
```

Arguments

x1	The first logical vector
x2	The second logical vector

Details

This function calculate Cohen's kappa score for two logical vectors.

Value

The Cohen's kappa score

make_DEG_data *Simulate differentially expressed gene data (Gaussian)*

Description

Generate differentially expressed gene (DEG) data from Gaussian distribution.

Usage

```
make_DEG_data(
  n.genes,
  n.samples.A,
  n.samples.B,
  exp.mean = 8,
  exp.sd = 2,
  alpha = 0.2,
  size.factor.sd = 0.1,
  ...
)
```

Arguments

n.genes	The total number of genes in the simulated data.
n.samples.A	The number of samples in the group A.
n.samples.B	The number of samples in the group B.
exp.mean	The mean of log-normal distribution that determines gene-specific expression mean.
exp.sd	The standard deviation of log-normal distribution that determines gene-specific expression means.
alpha	The dispersion ratio of gene-specific expression standard deviation to mean.
size.factor.sd	The standard deviation of size factors for samples.
...	The parameters passed to function make_DEG_pattern.

Details

The expression values of each gene are assumed following a Gaussian distribution with gene-specific mean, which follows a log-normal distribution. The size factor for each sample follows a Gaussian distribution with zero mean and specific standard deviation. The heterogeneity of gene expression data is simulated by using the function make_DEG_pattern.

Value

This function will return a list with the following components:

DEG	The matrix of simulated DEG pattern, which is generated by make_DEG_pattern.

countsA	The expression matrix of group A. Each row represents a gene and each column represents a sample.
countsB	The expression matrix of group B. Each row represents a gene and each column represents a sample.

---

make_DEG_data2 *Simulate differentially expressed gene data (Negative binomial)*

Description

Generate differentially expressed gene (DEG) data from negative binomial distribution.

Usage

```
make_DEG_data2(
  n.genes,
  n.samples.A,
  n.samples.B,
  exp.mean = 8,
  exp.sd = 2,
  dispersion = NULL,
  size.factor.sd = 0.1,
  ...
)
```

Arguments

n.genes	The total number of genes in the simulated data.
n.samples.A	The number of samples in the group A.
n.samples.B	The number of samples in the group B.
exp.mean	The mean of log-normal distribution that determines gene-specific expression mean.
exp.sd	The standard deviation of log-normal distribution that determines gene-specific expression mean.
dispersion	The dispersion parameter for negative binomial distribution. The default values are determined by the expression mean.
size.factor.sd	The standard deviation of size factors for samples.
...	The parameters passed to function make_DEG_pattern.

Details

The expression values of each gene are assumed following a negative binomial distribution with gene-specific mean, which follows a log-normal distribution. The size factor for each sample follows a Gaussian distribution with zero mean and specific standard deviation. The heterogeneity of gene expression data is simulated by using the function make_DEG_pattern.

Value

This function will return a list with the following components:

DEG	The matrix of simulated DEG pattern, which is generated by make_DEG_pattern.
countsA	The expression matrix of group A. Each row represents a gene and each column represents a sample.
countsB	The expression matrix of group B. Each row represents a gene and each column represents a sample.

---

make_DEG_pattern *Simulate differentially expressed gene pattern*

Description

Generate complicated differentially expressed gene (DEG) pattern to simulate varied degree of heterogeneity.

Usage

```
make_DEG_pattern(
  n.genes,
  n.samples,
  fold.change = 2,
  gene.rate = 0.3,
  sample.rate = 1,
  active.rate = 1,
  up.rate = 0.5
)
```

Arguments

n.genes	The total number of genes in the simulated data.
n.samples	The total number of samples in the simulated data.
fold.change	The fold change level of DEGs.
gene.rate	The proportion of DEGs to all genes.
sample.rate	The proportion of abnormal samples to all samples.
active.rate	The probability that a DEG is truely differentially expressed in an abnormal sample.
up.rate	The proportion of up-regulated DEGs to all DEGs.

Details

The heterogeneity of gene expression pattern is mainly controlled by two parameters: sample.rate and active.rate. If both parameters are equal to 1, the gene expression pattern will be homogeneous, otherwise heterogeneous.

Value

This function will return a list with the following components:

FC	The matrix of simulated fold changes. Each row represents a gene and each column represents a sample.
gene	The vector of gene status: 1 for up-regulated, -1 for down-regulated, and 0 for normal genes.
sample	The vector of sample status: 1 for abnormal, and 0 for normal samples.

---

markrank *MarkRank*

Description

MarkRank is a novel proposed network-based model, which can identify the cooperative biomarkers for heterogeneous complex disease diagnoses.

Usage

```
markrank(
  dataset,
  label,
  adj_matrix,
  alpha = 0.8,
  lambda = 0.2,
  eps = 1e-10,
  E_value = NULL,
  trace = TRUE,
  d = Inf,
  Given_NET2 = NULL
)
```

Arguments

dataset	The microarray expression matrix of related disease. Each row represents a sample and each column represents a gene.
label	The 0-1 binary phenotype vector of dataset samples. The size of label must accord with the sample number in dataset.
adj_matrix	The 0-1 binary adjacent matrix of a connected biological network. Here the node set should be the same order as the gene set in expression matrix.
alpha	The convex combination coefficient of network effect and prior information vector E_value. The range of alpha is in [0,1]. A larger alpha will lay more emphasis on the network information. The default value is 0.8.

lambda	In the random walk-based iteration, matrix A1 reflects the stucture information of the biological network, whereas matrix A2 reflects the cooperative effect of gene combinations. Parameter lambda is the convex combination coefficient of two network effects. The range of lambda is in [0,1]. A larger lambda will lay more emphasis on the A1. The default value is 0.2.
eps	The stop criteria for the iterative solution method. The default value is 1e-10.
E_value	A vector containing the prior information about the importance of nodes. Default is the absolute Pearson correlation coefficient (PCC).
trace	Locaical variable indicated whether tracing information on the progress of the gene cooperation network construction is produced.
d	Threshold for simplifying the G_2 computation. Only the gene pairs whose shortest distances in PPI network are less than d participate in the G_2 computation. The default value is Inf.
Given_NET2	Whether a computed cooperation network is given for tuning parameter. See Details for a more specific description.

Details

MarkRank is a network-based biomarker identification method to prioritize disease genes by integrating multi-source information including the biological network, e.g protein-protein interaction (PPI) network, the prior information about related diseases, and the discriminative power of cooperative gene combinations. MarkRank shows that explicit modeling of gene cooperative effects can greatly improve biomarker identification for complex disease, especially for diseases with high heterogeneity.

MarkRank algorithm contains mainly two steps: 1) The construction of gene cooperation network G_2 and 2) a random walk based iteration procedure. The following descriptions will help the users to using markrank more convenient:

1) As for the construction of the gene cooperation network, we suggest the user to set trace=TRUE to output the G_2 computation process. The G_2 construction step finished if the output number is identical to the gene number of the input expression matrix. The parameter d introduced the structure information of used biological network to facilitate the construction of G_2, only the gene pairs whose shortest distances in network are less than d participate the G_2 computation. We suggest d=Inf, the default value, to fully use the information of expression matrix. If the user given a preset d, the distance matrix of input network dis will be returned.

2) MarkRank uses a random-walk based iteration procedure to score each gene. The detailed formula is:

score = alpha*[lambda*A1 + (1-lambda)*A2]*score + (1-alpha)*E_value.

The users could set an appropriate parameter settings in their pracitical application. Our suggested value is alpha=0.8 and lambda=0.2. The model input parameter combinations and iteration steps will be returned in output components initial_pars and steps, respectively. Because the iteration step is separate with the cooperation network construction, the user can use the parameter Given_NET2 to tune the model parameters. In detail, the user could set

Given_NET2 = result$NET2

in markrank input to avoid the repeated computation of G_2, where the object result is the returned variable of markrank function.

3) The final MarkRank score for each gene is in output `score`. The users could sort this result and use the top ranked genes for further analysis.

Value

This function will return a list with the following components:

`score`	The vector of final MarkRank scores for each gene.
`steps`	The final iteration steps in random walk based scoring procedure.
`NET2`	The weighted adjacent matrix of gene cooperation network.
`initial_pars`	The initial/input parameter values used in MarkRank.
`dis`	The pairwise distance matrix of input network. This variable will be `Null` if input d=Inf.

`netDEG` *netDEG: Differentially expressed gene identification method*

Description

Perform netDEG for two group samples.

Usage

```
netDEG(
  ref.expr.matrix,
  expr.matrix,
  p.edge = 0.1,
  summarize = c("gene", "sample"),
  summarize.method = c("sumlog", "sumlog"),
  summarize.shrink = c(Inf, Inf),
  log.expr = FALSE,
  zero.as.dropout = TRUE,
  scale.degree = TRUE,
  use.parallel = FALSE
)
```

Arguments

`ref.expr.matrix`
: The reference expression matrix. Each row represents a gene and each column represents a sample.

`expr.matrix`
: The test expression matrix. Each row represents a gene and each column represents a sample.

`p.edge`
: The expected probability of edges in the expression ratio network for a normal sample.

`summarize`
: Character vector indicating how to summarize the results. Available methods are `c("gene", "sample")`.

`summarize.method`
: Character vector indicating the methods used to summarize the results. See `p_combine`.

`summarize.shrink`
: Numeric vector indicating the shrink parameter to summarize the results. See `p_combine`.

`log.expr`
: Logical variable indicating whether the input expression matrix is in logarithmic scale.

`zero.as.dropout`
: Logical variable indicating whether the zero expressions are regarded as dropouts.

`scale.degree`
: Logical variable indicating whether the degree values are scaled according to the dropout rate.

`use.parallel`
: Logical variable indicating to use the BiocParallel package to accelerate computation.

Value

This function will return a list with the following components:

`up`
: A numeric matrix with same dimension as `expr.matrix`, containing the p-values of up-regulation test.

`down`
: A numeric matrix with same dimension as `expr.matrix`, containing the p-values of down-regulation test.

`twoside`
: A numeric matrix with same dimension as `expr.matrix`, containing the p-values of twoside test.

`rev`
: A list containing the reverse comparison results, containing three components: `up`, `down`, and `twoside`. Available if the gene method is specified in `summarize` argument.

`gene`
: A list containing the gene-wise summaried results, containing three components: `up`, `down`, and `twoside`. Available if the gene method is specified in `summarize` argument.

`sample`
: A list containing the sample-wise summaried results, containing three components: `up`, `down`, and `twoside`. Available if the sample method is specified in `summarize` argument.

netDEG_pvalue *Calculate netDEG p-values*

Description

Perform the single or two side tests and calculate the p-values.

Usage

```
netDEG_pvalue(ref.ratio.dist, expr.val, log.expr = FALSE, scale.degree = FALSE)
```

Arguments

ref.ratio.dist	The expression ratio distribution profile returned by get_ratio_distribution or get_ratio_distribution2.
expr.val	Numeric vector of gene expression values in the sample.
log.expr	Logical variable indicating whether the input expression vector is in logarithmic scale.
scale.degree	Logical variable indicating whether the degree values are scaled according to the dropout rate.

Value

This function will return a list with the following components:

up	A numeric vector containing the p-values of up-regulation test.
down	A numeric vector containing the p-values of down-regulation test.
twoside	A numeric vector containing the p-values of twoside test.

net_align *Network alignment method based on conditional random fields*

Description

Find the maximal matching subnetworks from a target network for a query network based on the conditional random fields (CRF) model.

Usage

```
net_align(
  query.net,
  target.net,
  node.sim,
  query.type = 4,
  delta.d = 1e-10,
  delta.c = 0.5,
  delta.e = 1,
  delta.s = 1,
  output = "result.txt"
)
```

Arguments

query.net	The input file name of the query network.
target.net	The input file name of the target network.
node.sim	The input file name of the node similarity scores between the query network and the target network.
query.type	The querying network type: 1 - general, 2 - chain, 3 - tree, 4 - heuristic.
delta.d	The parameter delta.d is a parameter for deletions.
delta.c	The parameter delta.c is a parameter for consecutive deletions.
delta.e	The parameter delta.e is a parameter for single deletion.
delta.s	The parameter delta.s is a parameter for insertions.
output	The suffix of output file name. The output contains two files in the working directory. One is the matching nodes and edges between query network and target network, the other is the unique matching node pairs.

Details

This is an approach for network alignment problem based on conditional random field (CRF) model which uses the node similarity and structure information equally. This method is based on our network querying method net_query. This method uses an iterative strategy to get the one-to-one map between the query network and target netowrk.

More details can be seen in net_query.

Examples

```
## Not run:
library(Corbi)

## An example: "querynet.txt", "targetnet.txt", "nodesim.txt" are
## three input files in the working directory
net_align("querynet.txt", "targetnet.txt", "nodesim.txt")

## End(Not run)
```

---

net_query *Network querying method based on conditional random fields*

Description

Find the best matching subnetworks from a large target network for small query networks based on the conditional random fields (CRF) model.

Usage

```
net_query(
  query.net,
  target.net,
  node.sim,
  query.type = 4,
  delta.d = 1e-10,
  delta.c = 0.5,
  delta.e = 1,
  delta.s = 1,
  output = "result.txt"
)

net_query_batch(
  query.nets,
  target.net,
  node.sim,
  query.type = 4,
  delta.d = 1e-10,
  delta.c = 0.5,
  delta.e = 1,
  delta.s = 1,
  output = "result.txt"
)
```

Arguments

query.net	The input file name of the query network.
target.net	The input file name of the target network.
node.sim	The input file name of the node similarity scores between the query network and the target network.
query.type	The querying network type: 1 - general, 2 - chain, 3 - tree, 4 - heuristic.
delta.d	The parameter delta.d is a parameter for deletions.
delta.c	The parameter delta.c is a parameter for consecutive deletions.
delta.e	The parameter delta.e is a parameter for single deletion.
delta.s	The parameter delta.s is a parameter for insertions.
output	The suffix of output file name.
query.nets	The vector of input file names of the query networks.

Details

This is an approach for network querying problem based on conditional random field (CRF) model which can handle both undirected and directed networks, acyclic and cyclic networks, and any number of insertions/deletions.

When querying several networks in the same target network, net_query_batch will save much time.

- query.net: The query network file is written as follows:
  v1 v2 v3 v4 v5
  v3 v4
  ...
  where v1, v2, v3, v4, v5 ... are the nodes' names and each line indicates there are edges between the first node and other nodes in the line. For example, the first line denotes 4 edges: (v1, v2), (v1, v3), (v1, v4), and (v1, v5).
- target.net: The format of this file is the same as the query network file.
- node.sim: This similarity file's format is as follows:
  v1 V1 s1
  v1 V2 s2
  ...
  v1 is the node from the query network, V1 is the node from the target network, s1 is the similarity score between the node v1 and V1, and so on.
- query.type: If query.type = 1, the loopy belief propagation (LBP) algorithm will be applied, which is an approximate algorithm for a general graph with loops. If the query is a chain or tree, there are exact algorithms. Set query.type = 2 when the query is a chain, and query.type = 3 when the query is a tree. The heuristic algorithm will be used when query.type = 4, which will try the exact algorithm (junction tree algorithm) first and resort to LBP algorithm when the exact algorithm failed. The default value is 4.
- delta.d: The smaller delta.d is, the heavier penalty for deletions.
- delta.c: The smaller delta.c is, the heavier penalty for consecutive deletions.
- delta.e: The smaller delta.e is, the heavier penalty for single deletion.
- delta.s: The larger delta.s indicates heavier penalty for insertions.

nnzero *The number of non-zero values of a submatrix*

Description

Retuen the number of non-zero values of the specified submatrix of a given sparse matrix rapidly

Usage

```
nnzero(m, rows = 1:dim(m)[1], cols = 1:dim(m)[2])
```

Arguments

m	The matrix
rows	The integer vector of row index(es) or logical vector indicated the selected rows
cols	The integer vector of column index(es) or logical vector indicated the selected cols

Details

This function implements faster calculation algorithm for the CsparseMatrix and RsparseMatrix class in the package **Matrix**.

Value

This function will return the number of non-zero values in the specified submatrix.

`pmultihyper` *The Multivariate Hypergeometric Distribution*

Description

The distribution function for the weighted sums of multivariate hypergeometric distribution

Usage

```
pmultihyper(x, k, m, w)
```

Arguments

`x`	The quantile of weighted sum.
`k`	The total number of balls drawn from the urn.
`m`	Integer non-negative vector of length N, containing the number of balls of each color in the urn. N is the number of colors.
`w`	Numeric non-negative vector of length N, specifying the weight of balls of each color.

Details

This function gives the distribution function for the weighted sums of multivariate hypergeometric distribution by recursively calling the hypergeometric distribution density function `dhyper`.

Value

This function will return the probablity of $P(X \leq x)$.

See Also

`dhyper`

pmultinom *The Multinomial Distribution*

Description

The distribution function for the weighted sums of multinomial distribution

Usage

```
pmultinom(x, k, m, w)
```

Arguments

x	The quantile of weighted sum.
k	The total number of balls drawn from the urn.
m	Numeric non-negative vector of length N, specifying the probability for drawing the ball of each color; is internally normalized to sum 1. Infinite and missing values are not allowed. N is the number of colors.
w	Numeric non-negative vector of length N, specifying the weight of balls of each color.

Details

This function gives the distribution function for the weighted sums of multinomial distribution by recursively calling the binomial distribution density function dbinom.

Value

This function will return the probablity of $P(X \leq x)$.

See Also

dbinom, dmultinom, rmultinom

p_combine *Calculate combined p-value*

Description

Combine the statistical significance results from several independent tests by using one of several methods.

Usage

```
p_combine(p, method = "sumlog", shrink = Inf)
```

Arguments

p	the numeric vector containing the p-values need to combine.
method	the method use to combine the p-values, can be "sumlog" (Fisher's method), "sumz" (Stouffer's method).
shrink	the number of p-values used in calculation, which are uniform selected from original p-value vector.

Value

This function will return a list with the following components:

p	The combined p-value.
v	The value of statistic.
chisq	Use "sumlog" method: The value of chi-squared statistic.
df	Use "sumlog" method: The degrees of freedom of chi-squared distribution.
z	Use "sumz" method: The value of sum z statistic.

---

read_net *Read network information from text file*

Description

Read the network information from a text file with specific format.

Usage

```
read_net(file)
```

Arguments

file	The name of text file

Details

This function reads the network information from a text file with specific format: each line contains two strings separated by spaces, which correspond to the names of two end points of one edge in the network.

Value

A list with the following components:

size	The number of network nodes
node	The vector of network node names
matrix	The logical adjacency matrix

See Also

write_net

`rmultihyper` *The Multivariate Hypergeometric Distribution*

Description

Generate random variables for the multivariate hypergeometric distribution

Usage

```
rmultihyper(n, k, m)
```

Arguments

`n`	The number of observations.
`k`	The total number of balls drawn from the urn.
`m`	The integer vector containing the number of balls of each color in the urn. Length of vector is the number of colors.

Details

This function generates random variables for the multivariate hypergeometric distribution by iteratively calling hypergeometric random variable generator `rhyper`.

Value

This function will return a matrix of `length(m)` rows and `n` columns, and each column contains the number of balls of each color drawn from the urn.

See Also

rhyper

`simulate_dropout` *Simulate dropout expression data*

Description

Generate the expression data with desired dropout rate

Usage

```
simulate_dropout(counts, dropout.rate = 0, dropout.rate.sd = 0.1)
```

Arguments

`counts`	expression matrix where each row is a gene and each column is a sample.
`dropout.rate`	the desired average dropout rate of all samples.
`dropout.rate.sd`	the desired standard deviation of dropout rate among samples.

Details

The dropout event is modelled by a logistic distribution such that the low expression genes have higher probability of dropout. The expression value of genes in a sample are randomly set to zero with probabilities associated with their true expression values until the desired dropout rate for that sample is meet.

Value

This function will return a list with the following components:

`counts`	The modified expression matrix with the same dimension as input `counts`.
`original.counts`	The original input expression matrix.
`dropout`	The binary matrix indicating where the dropout events happen.

Peter V. Kharchenko, Lev Silberstein, and David T. Scadden. Bayesian approach to single-cell differential expression analysis. Nature Methods, 11(7):740–742, 2014.

`simulate_dropout2` *Simulate dropout expression data*

Description

Generate the expression data with desired dropout rate range

Usage

```
simulate_dropout2(counts, min.rate = 0, max.rate = 0.8)
```

Arguments

`counts`	expression matrix where each row is a gene and each column is a sample.
`min.rate`	the minimum dropout rate of all samples.
`max.rate`	the maximum dropout rate of all samples.

Details

The dropout event is modelled by a logistic distribution such that the low expression genes have higher probability of dropout. The expression value of genes in a sample are randomly set to zero with probabilities associated with their true expression values until the desired dropout rate for that sample is meet.

Value

This function will return a list with the following components:

`counts`	The modified expression matrix with the same dimension as input `counts`.
`original.counts`	The original input expression matrix.
`dropout`	The binary matrix indicating where the dropout events happen.

simulate_sample_groups *Simulate sample groups from given samples with labels*

Description

Generate sample groups with desired labels and sizes from given sample labels.

Usage

```
simulate_sample_groups(labels, groups, sizes, replace = FALSE)
```

Arguments

labels	a vector containing the label of each sample in the pool.
groups	a vector containing the desired label of samples in each group. The label must be available in the sample pool provided by labels.
sizes	integer vector indicating the desired number of samples in each group. The length must be either one or the same as groups.
replace	logical variable indicating whether sampling is with replacement.

Value

This function will return a list with the same length as groups. Each component is a vector containing the indexes of samples that are sampled for the corresponding group.

submatrix *Extract a submatrix from a matrix*

Description

Extract a specified submatrix from a sparse matrix rapidly

Usage

```
submatrix(m, rows, cols)
```

Arguments

m	The matrix
rows	The integer vectors of row index(es)
cols	The integer vectors of column index(es)

Details

This function implements faster submatrix extraction algorithm for the CsparseMatrix class in the package **Matrix**.

Value

This function will return the specified submatrix as a matrix of corresponding type.

URG_getFactor *Calculate normalization factors for URG method*

Description

Calculate the normalization factor for each sample by using URG (uniform ratio graph) method.

Usage

```
URG_getFactor(expr.matrix, p.edge = 0.25, p.gene = 0.4, log.expr = FALSE)
```

Arguments

expr.matrix	The expression matrix. Each row represents a gene and each column represents a sample.
p.edge	The percentage of gene pairs that are selected into the uniform ratio graph.
p.gene	The maximal percentage of genes that are selected as the stable genes.
log.expr	Logical variable indicating whether the input expression matrix is in logarithmic scale.

Value

This function will return a numeric vector with each element [i] represents the normalization factor of sample (i).

References

Xinhan Ye, Ling-Yun Wu. URG: a new normalization method for gene expression data based on graph model. Manuscript.

See Also

URG_normalize

URG_normalize *Normalize using given factors*

Description

Normalize the expression matrix by using the given factor for each sample.

Usage

```
URG_normalize(expr.matrix, factor, log.expr = FALSE)
```

Arguments

expr.matrix	The expression matrix. Each row represents a gene and each column represents a sample.
factor	The numeric vector of normalization factors.
log.expr	Logical variable indicating whether the input expression matrix is in logarithmic scale.

Value

This function will return a numeric matrix with the same dimension of `expr.matrix`.

See Also

URG_getFactor

write_net *Write network information to text file*

Description

Write the network information to a text file with specific format.

Usage

```
write_net(net, file)
```

Arguments

net	A list as returned by read_net
file	The name of text file

Details

This function writes the network information to a text file with specific format: each line contains two strings separated by spaces, which correspond to the names of two end points of one edge in the network.

See Also

read_net
